

STAT253/317 Lecture 3: Two key questions

1. As time goes to infinity, does the fraction of time spent in a given state converge? Mathematically, we aim to study

$$\lim_{n \rightarrow \infty} \frac{\sum_{i=0}^{n-1} 1\{X_i = k\}}{n}.$$

2. As time goes to infinity, does the probability of being in a given state converge to a limit? This is given by

$$\lim_{n \rightarrow \infty} P_{ij}^{(n)}.$$

Stationary Distribution

Define $\pi_i^{(n)} = P(X_n = i)$, $i \in \mathfrak{X}$ to be the marginal distribution of X_n , $n = 1, 2, \dots$, and let $\pi^{(n)}$ be the row vector

$$\pi^{(n)} = (\pi_0^{(n)}, \pi_1^{(n)}, \pi_2^{(n)}, \dots),$$

From Chapman-Kolmogorov Equation, we know that

$$\pi^{(n)} = \pi^{(n-1)}\mathbb{P} \quad \text{i.e.} \quad \pi_j^{(n)} = \sum_{i \in \mathfrak{X}} \pi_i^{(n-1)} P_{ij} \text{ for all } j \in \mathfrak{X},$$

If π is a distribution on \mathfrak{X} satisfying

$$\pi\mathbb{P} = \pi \quad \text{i.e.} \quad \pi_j = \sum_{i \in \mathfrak{X}} \pi_i P_{ij} \text{ for all } j \in \mathfrak{X},$$

then $\pi^{(0)} = \pi$ implies $\pi^{(n)} = \pi$ for all n .

We say π is a **stationary distribution** of the Markov chain.

Example 1: 2-state Markov Chain

$$\mathfrak{X} = \{0, 1\}, \quad \mathbb{P} = \begin{matrix} & \begin{matrix} 0 & 1 \end{matrix} \\ \begin{matrix} 0 \\ 1 \end{matrix} & \begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix} \end{matrix}$$

$$\begin{aligned} \pi \mathbb{P} = \pi &\Rightarrow \begin{cases} \pi_0 &= (1 - \alpha)\pi_0 + \beta\pi_1 \\ \pi_1 &= \alpha\pi_0 + (1 - \beta)\pi_1 \end{cases} \\ &\Rightarrow \begin{cases} \alpha\pi_0 &= \beta\pi_1 \\ \beta\pi_1 &= \alpha\pi_0 \end{cases} \end{aligned}$$

Need one more constraint: $\pi_0 + \pi_1 = 1$

$$\Rightarrow \pi = (\pi_0, \pi_1) = \left(\frac{\beta}{\alpha + \beta}, \frac{\alpha}{\alpha + \beta} \right)$$

Example 2: Ehrenfest Diffusion Model with N Balls

$$P_{ij} = \begin{cases} \frac{i}{N} & \text{if } j = i - 1 \\ \frac{N-i}{N} & \text{if } j = i + 1 \\ 0 & \text{otherwise} \end{cases}$$

$$\pi_0 = \pi_1 P_{10} = \frac{1}{N} \pi_1 \Rightarrow \pi_1 = N \pi_0 = \binom{N}{1} \pi_0$$

$$\pi_1 = \pi_0 P_{01} + \pi_2 P_{21} = \pi_0 + \frac{2}{N} \pi_2 \Rightarrow \pi_2 = \frac{N(N-1)}{2} \pi_0 = \binom{N}{2} \pi_0$$

$$\pi_2 = \pi_1 P_{12} + \pi_3 P_{32} = \frac{N-1}{N} \pi_1 + \frac{3}{N} \pi_3 \Rightarrow \pi_3 = \frac{N(N-1)(N-2)}{6} \pi_0 = \binom{N}{3} \pi_0$$

\vdots

\vdots

In general, you'll get $\pi_i = \binom{N}{i} \pi_0$.

As $1 = \sum_{i=0}^N \pi_i = \pi_0 \sum_{i=0}^N \binom{N}{i}$ and $\sum_{i=0}^N \binom{N}{i} = 2^N$, we have

$$\pi_i = \binom{N}{i} \left(\frac{1}{2}\right)^N \quad \text{for } i = 0, 1, 2, \dots, N.$$

Stationary Distribution May Not Be Unique

Consider a Markov chain with transition matrix \mathbb{P} of the form

$$\mathbb{P} = \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} * & * & 0 & 0 & 0 \\ * & * & 0 & 0 & 0 \\ 0 & 0 & * & * & * \\ 0 & 0 & * & * & * \\ 0 & 0 & * & * & * \end{pmatrix} \end{matrix} = \begin{pmatrix} \mathbb{P}_x & 0 \\ 0 & \mathbb{P}_y \end{pmatrix}$$

This Markov chain has 2 classes $\{0,1\}$ and $\{2, 3, 4\}$; both are recurrent. Note that this Markov chain can be reduced to two sub-Markov chains, one with state space $\{0,1\}$ and the other $\{2, 3, 4\}$. Their transition matrices are respectively \mathbb{P}_x and \mathbb{P}_y .

Say $\pi_x = (\pi_0, \pi_1)$ and $\pi_y = (\pi_2, \pi_3, \pi_4)$ be respectively the stationary distributions of the two sub-Markov chains, i.e.,

$$\pi_x \mathbb{P}_x = \pi_x, \quad \pi_y \mathbb{P}_y = \pi_y$$

Verify that $\pi = (c\pi_0, c\pi_1, (1-c)\pi_2, (1-c)\pi_3, (1-c)\pi_4)$ is a stationary distribution of $\{X_n\}$ for any c between 0 and 1.

Not All Markov Chains Have a Stationary Distribution

For one-dimensional symmetric random walk, the transition probabilities are

$$P_{i,i+1} = P_{i,i-1} = 1/2$$

The stationary distribution $\{\pi_j\}$ would satisfy the equation:

$$\pi_j = \sum_{i \in \mathcal{X}} \pi_i P_{ij} = \frac{1}{2}\pi_{j-1} + \frac{1}{2}\pi_{j+1}.$$

Once π_0 and π_1 are determined, all π_j 's can be determined from the equations as

$$\pi_j = \pi_0 + (\pi_1 - \pi_0)j, \quad \text{for all integer } j.$$

As $\pi_j \geq 0$ for all integer j , $\Rightarrow \pi_1 = \pi_0$. Thus

$$\pi_j = \pi_0 \quad \text{for all integer } j$$

Impossible to make $\sum_{j=-\infty}^{\infty} \pi_j = 1$.

Conclusion: 1-dim symmetric random walk does not have a stationary distribution.

Limiting Distribution

A probability distribution $\pi = [\pi_0, \pi_1, \pi_2, \dots]$ is called the limiting distribution of a Markov chain X_n if for all $i, j \in \mathfrak{X}$,

$$\pi_j = \lim_{n \rightarrow \infty} P_{ij}^{(n)} = \lim_{n \rightarrow \infty} \mathbb{P}(X_n = j \mid X_0 = i)$$

Matrix version

$$\text{i.e., } \lim_{n \rightarrow \infty} \mathbb{P}^{(n)} = \begin{pmatrix} \pi_0 & \pi_1 & \pi_2 & \pi_3 & \cdots \\ \pi_0 & \pi_1 & \pi_2 & \pi_3 & \cdots \\ \pi_0 & \pi_1 & \pi_2 & \pi_3 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}$$

Example: Two-State Markov Chain

$$\mathcal{X} = \{0, 1\}, \quad \mathbb{P} = \begin{matrix} & \begin{matrix} 0 & 1 \end{matrix} \\ \begin{matrix} 0 \\ 1 \end{matrix} & \begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix} \end{matrix}$$

By induction, one can show that

$$\begin{aligned} \mathbb{P}^{(n)} &= \begin{pmatrix} \frac{\beta}{\alpha + \beta} + \frac{\alpha}{\alpha + \beta}(1 - \alpha - \beta)^n & \frac{\alpha}{\alpha + \beta} - \frac{\alpha}{\alpha + \beta}(1 - \alpha - \beta)^n \\ \frac{\beta}{\alpha + \beta} + \frac{\beta}{\alpha + \beta}(1 - \alpha - \beta)^n & \frac{\alpha}{\alpha + \beta} - \frac{\beta}{\alpha + \beta}(1 - \alpha - \beta)^n \end{pmatrix} \\ &\rightarrow \begin{pmatrix} \frac{\beta}{\alpha + \beta} & \frac{\alpha}{\alpha + \beta} \\ \frac{\beta}{\alpha + \beta} & \frac{\alpha}{\alpha + \beta} \end{pmatrix} \quad \text{as } n \rightarrow \infty \end{aligned}$$

The limiting distribution π is $(\frac{\beta}{\alpha + \beta}, \frac{\alpha}{\alpha + \beta})$.

Limiting Distribution is a Stationary Distribution

The limiting distribution of a Markov chain is a stationary distribution of the Markov chain.

Proof (*not rigorous*). By Chapman Kolmogorov Equation,

$$P_{ij}^{(n+1)} = \sum_{k \in \mathfrak{X}} P_{ik}^{(n)} P_{kj}$$

Letting $n \rightarrow \infty$, we get

$$\begin{aligned} \pi_j &= \lim_{n \rightarrow \infty} P_{ij}^{(n+1)} = \lim_{n \rightarrow \infty} \sum_{k \in \mathfrak{X}} P_{ik}^{(n)} P_{kj} \\ &\stackrel{*}{=} \sum_{k \in \mathfrak{X}} \lim_{n \rightarrow \infty} P_{ik}^{(n)} P_{kj} \quad (\text{needs justification}) \\ &= \sum_{k \in \mathfrak{X}} \pi_k P_{kj} \end{aligned}$$

Thus the limiting distribution π_j 's satisfies the equations $\pi_j = \sum_{k \in \mathfrak{X}} \pi_k P_{kj}$ for all $j \in \mathfrak{X}$ and is a stationary distribution.

See Karlin & Taylor (1975), Theorem 1.3 on p.85-86 for a rigorous proof.

Not All Markov Chains Have Limiting Distributions

Consider the simple random walk X_n on $\{0, 1, 2, 3, 4\}$ with absorbing boundary at 0 and 4. That is,

$$X_{n+1} = \begin{cases} X_n + 1 & \text{with probability 0.5 if } 0 < X_n < 4 \\ X_n - 1 & \text{with probability 0.5 if } 0 < X_n < 4 \\ X_n & \text{if } X_n = 0 \text{ or } 4 \end{cases}$$

The transition matrix is hence

$$\mathbb{P} = \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0.5 & 0 & 0.5 & 0 & 0 \\ 0 & 0.5 & 0 & 0.5 & 0 \\ 0 & 0 & 0.5 & 0 & 0.5 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \end{matrix}$$

Not All Markov Chains Have Limiting Distributions

The n -step transition matrix of the simple random walk X_n on $\{0, 1, 2, 3, 4\}$ with absorbing boundary at 0 and 4 can be shown by induction using the Chapman-Kolmogorov Equation to be

$$\mathbb{P}^{(2n-1)} = \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0.75 - 0.5^{n+1} & 0 & 0.5^n & 0 & 0.25 - 0.5^{n+1} \\ 0.5 - 0.5^n & 0.5^n & 0 & 0.5^n & 0.5 - 0.5^n \\ 0.25 - 0.5^{n+1} & 0 & 0.5^n & 0 & 0.75 - 0.5^{n+1} \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \end{matrix}$$
$$\mathbb{P}^{(2n)} = \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0.75 - 0.5^{n+1} & 0.5^{n+1} & 0 & 0.5^{n+1} & 0.25 - 0.5^{n+1} \\ 0.5 - 0.5^{n+1} & 0 & 0.5^n & 0 & 0.5 - 0.5^{n+1} \\ 0.25 - 0.5^{n+1} & 0.5^{n+1} & 0 & 0.5^{n+1} & 0.75 - 0.5^{n+1} \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \end{matrix}$$

Not All Markov Chains Have Limiting Distributions

The limit of the n -step transition matrix as $n \rightarrow \infty$ is

$$\mathbb{P}^{(n)} \rightarrow \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \left(\begin{array}{ccccc} 1 & 0 & 0 & 0 & 0 \\ 0.75 & 0 & 0 & 0 & 0.25 \\ 0.5 & 0 & 0 & 0 & 0.5 \\ 0.25 & 0 & 0 & 0 & 0.75 \\ 0 & 0 & 0 & 0 & 1 \end{array} \right) \end{matrix}.$$

Though $\lim_{n \rightarrow \infty} P_{ij}^{(n)}$ exists but the limit depends on the initial state i , this Markov chain has no limiting distribution.

This Markov chain has two distinct absorbing states 0 and 4. Other transient states may be absorbed to either 0 or 4 with different probabilities depending how close those states are to 0 or 4.

When does a Markov chain have limiting distribution?

Periodicity

A state of a Markov chain is said to have **period** d if

$$P_{ii}^{(n)} = 0, \quad \text{whenever } n \text{ is not a multiple of } d$$

In other words, d is the *greatest common divisor* of all the n 's such that

$$P_{ii}^{(n)} > 0$$

We say a state is **aperiodic** if $d = 1$, and **periodic** if $d > 1$.

Fact: Periodicity is a class property.

That is, all states in the same class have the same period.

For a proof, see Problem 2&3 on p.77 of Karlin & Taylor (1975).

Examples (Periodicity)

- ▶ All states in the Ehrenfest diffusion model are of period $d = 2$ since it's impossible to move back to the initial state in odd number of steps.
- ▶ 1-D (2-D) Simple random walk on all integers (grids on a 2-d plane) are of period $d = 2$

Example (Periodicity)

Specify the classes of a Markov chain with the following transition matrix, and find the periodicity for each state.

$$\begin{array}{c} \begin{array}{ccccccc} & 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ \begin{array}{l} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 6 \\ 7 \end{array} & \left(\begin{array}{ccccccc} 0 & 0.5 & 0 & 0.5 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0.5 & 0 & 0 & 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0.5 & 0 & 0.5 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0.1 & 0.9 \\ 0 & 0 & 0 & 0 & 0 & 0.7 & 0.3 \end{array} \right) \end{array} \end{array}$$

Classes: $\{1,2,3,4,5\}$, $\{6,7\}$.

Period is $d = 1$ for state 6 and 7.

Period is $d = 3$ for state 1,2,3,4,5 since
 $\{1\} \rightarrow \{2,4\} \rightarrow \{3,5\} \rightarrow \{1\}$.

Periodic Markov Chains Have No Limiting Distributions

For example, in the Ehrenfest diffusion model with 4 balls, it can be shown by induction that the $(2n - 1)$ -step transition matrix is

$$\mathbb{P}^{(2n-1)} = \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \left(\begin{array}{ccccc} 0 & 1/2+1/2^{2n-1} & 0 & 1/2-1/2^{2n-1} & 0 \\ 1/8+1/2^{2n+1} & 0 & 3/4 & 0 & 1/8-1/2^{2n+1} \\ 0 & 1/2 & 0 & 1/2 & 0 \\ 1/8-1/2^{2n+1} & 0 & 3/4 & 0 & 1/8+1/2^{2n+1} \\ 0 & 1/2-1/2^{2n-1} & 0 & 1/2+1/2^{2n-1} & 0 \end{array} \right) \end{matrix}$$

$$\rightarrow \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \left(\begin{array}{ccccc} 0 & 1/2 & 0 & 1/2 & 0 \\ 1/8 & 0 & 3/4 & 0 & 1/8 \\ 0 & 1/2 & 0 & 1/2 & 0 \\ 1/8 & 0 & 3/4 & 0 & 1/8 \\ 0 & 1/2 & 0 & 1/2 & 0 \end{array} \right) \end{matrix} \quad \text{as } n \rightarrow \infty.$$

Periodic Markov Chains Have No Limiting Distributions

and the $2n$ -step transition matrix is

$$\mathbb{P}^{(2n)} = \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} 1/8+1/2^{2n+1} & 0 & 3/4 & 0 & 1/8-1/2^{2n+1} \\ 0 & 1/2+1/2^{2n+1} & 0 & 1/2-1/2^{2n+1} & 0 \\ 1/8 & 0 & 3/4 & 0 & 1/8 \\ 0 & 1/2-1/2^{2n+1} & 0 & 1/2+1/2^{2n+1} & 0 \\ 1/8-1/2^{2n+1} & 0 & 3/4 & 0 & 1/8+1/2^{2n+1} \end{pmatrix} \end{matrix}$$

$$\rightarrow \begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} 1/8 & 0 & 3/4 & 0 & 1/8 \\ 0 & 1/2 & 0 & 1/2 & 0 \\ 1/8 & 0 & 3/4 & 0 & 1/8 \\ 0 & 1/2 & 0 & 1/2 & 0 \\ 1/8 & 0 & 3/4 & 0 & 1/8 \end{pmatrix} \end{matrix} \quad \text{as } n \rightarrow \infty.$$

Periodic Markov Chains Have No Limiting Distributions

In general for Ehrenfest diffusion model with N balls, as $n \rightarrow \infty$,

$$P_{ij}^{(2n)} \rightarrow \begin{cases} 2 \binom{N}{j} \left(\frac{1}{2}\right)^N & \text{if } i+j \text{ is even} \\ 0 & \text{if } i+j \text{ is odd} \end{cases}$$
$$P_{ij}^{(2n+1)} \rightarrow \begin{cases} 0 & \text{if } i+j \text{ is even} \\ 2 \binom{N}{j} \left(\frac{1}{2}\right)^N & \text{if } i+j \text{ is odd} \end{cases}$$

$\lim_{n \rightarrow \infty} P_{ij}^{(n)}$ doesn't exist for all $i, j \in \mathfrak{X}$

Summary

- ▶ Stationary distribution may not be unique if the Markov chain is not irreducible
- ▶ Stationary distribution may not exist
- ▶ A limiting distribution is always a stationary distribution
- ▶ If it exists, limiting distribution is unique
- ▶ Limiting distribution do not exist if the Markov chain is periodic
